Mobile Banking - Feature Portfolio Brief

1. Product Intent

This brief describes feature-level outcomes for a mobile banking portfolio. The source organization plans delivery around features rather than a hierarchy of formal requirements and Jira stories. The application should still normalize the artifacts into common delivery concepts.

2. Feature Outcomes

Feature	Outcome	Critical Consideration
Card Controls	Freeze/unfreeze cards	Fraud lock and step-up authentication
Travel Notice	Declare upcoming travel	Date windows and country validation
Secure Messages	Protected customer-support communication	Retention and attachment controls
Biometric Step-Up	Stronger verification for high-risk actions	Fallback and device trust

3. Card Controls

Customers may freeze a card immediately. Unfreezing is normally allowed after authentication, but an approved security change requires step-up verification when the freeze originated from a fraud lock. Existing tests that assume direct unfreeze may therefore be stale.

4. Travel Notice

Customers may declare travel dates and countries before departure. Validation must prevent impossible date ranges and unsupported country values. The business may expand the maximum advance-notice window in a future train, so tests should remain traceable to the active rule.

5. Secure Messages

Secure messages allow customers and support agents to exchange protected communication. Attachments require malware scanning, and retention behavior is governed separately from the user-facing feature description.

6. Biometric Step-Up

High-risk actions may require biometric or equivalent stronger verification. The requirement is conditional: low-risk actions should not always trigger the same friction. Delivery tests should therefore include both trigger and non-trigger scenarios.

7. Quality Expectations

- Every committed P0 feature requires current regression evidence.
- Security-sensitive changes require traceability to security validation.
- Subjective wording should be surfaced for clarification rather than silently converted into invented thresholds.

8. Feature-Centric Traceability

Feature Code is the stable product reference in this source system. User-story JSON, regression tests, change requests, and release-scope workbooks use the feature code differently. The onboarding layer should map these variations into a common representation.

9. Release Train Boundaries

Train-7 and Train-8 contain different feature scope. A future change should not automatically affect the current release unless the release-scope artifact indicates that the change has been accepted into the train.

10. Human Review

AI-generated clarifications or candidate test cases should remain reviewable. The system should assist product and QA teams without silently redefining regulated or security-sensitive business intent.
